# **Packages**

# **Background and Goals**

This data was collected April - May 2021 during a course-based undergraduate research experience (CURE) in Dr. Emily Taylor's Herpetology class of Spring Quarter 2021 at Cal Poly, San Luis Obispo. This part of the study was conducted to describe the variation of osmoregulation (cutaneous evaporative water loss) and osmotic balance (plasma osmolality and hematocrit) in *Sceloporus occidentalis* and to investigate what drives that variation. Please refer to **doi:** for full details.

## Data

#### Morphometrics and Blood Data

This data was collected upon capture of each lizard.

Variables in this dataframe: - date - collection/capture time for each lizard - individual ID for each lizard - sock ID used to capture each lizard (removed, not relevant to analyses) - SVL = snout-vent length - mass in

grams - sex - if female, whether or not gravid (with eggs) - which eye the blood sample was taken from - percent hematocrit = percent of blood that's red blood cells - osmolality = the concentration of solutes in the blood (this is the average of 1-3 replicates) - cloacal temperature at the time of CEWL measurement - processing time for each lizard, when all measurements were finished - hemolyzed = whether or not red blood cells burst and contaminated plasma

Before loading in this data, some incorrectly-measured hematocrit and osmolality were omitted: - hematocrit for individuals 1-16, due to observer error - osmolality for individual 19, due to instrumental error

```
# load and format data
morpho_blood_dat <- read.csv("./data/Herpetology_Data.csv", # filename
                             na.strings=c("","NA") # fix empty cells
                             ) %>%
  dplyr::mutate(# put date and time together
                collect_date_time = (paste(date, collect_time)),
                # replace some date-time values that have missing times
                collect_date_time = replace(collect_date_time,
                                             collect_date_time == "4/5/21 NA", NA),
                # correctly format date-time variable
                collect_date_time = as.POSIXct(collect_date_time,
                                                format = \frac{m}{d} \frac{M}{d} \frac{M}{M},

I want to test if any IDs are missing, and which ones if so.
test <- c(seq(1, 150, by = 1))
lost <- test[test %nin% morpho_blood_dat$individual_ID]</pre>
lost
```

Individuals 23 and 56 actually both do not exist because those numbers were skipped when assigning IDs, so we have all the individuals measured in the dataframe.

#### **CEWL Data**

First, load it all in and merge.

Variables in this dataframe are: - date - time - date\_time combined variable - individual\_ID for each lizard measured - region = where on the body CEWL was measured - TEWL\_g\_m2h = CEWL measurement value in grams/sq-meter/hour - ambient\_temp\_C = temperature when and where measurement was taken - ambient\_RH\_percent = relative humidity when and where measurement was taken - e\_s\_kPa = saturation vapor pressure at a given temperature (calculated using the Clausius-Clapeyron equation from Riddell et al. 2017, cited in the published paper using this data) - e\_a\_kPa = actual ambient vapor pressure (e\_a = e\_s \* RH proportion) - VPD\_kPa = vapor pressure deficit, which is essentially the drying power of the air (VPD = e\_s - e\_a)

#### Weather Data

This data was obtained from http://www.itrc.org/databases/precip/ (Adcon Server Data) to test the effect of ambient conditions on CEWL. This is different from the ambient conditions already measured with CEWL, which are the temperature and humidity around the measurement device at the time of measurement. We think that the temperature, humidity, wind speed, and solar radiation the lizard was exposed to prior to capture may also affect CEWL.

We didn't have a daylight savings time switchover during this study, so we don't need to worry about incorporating.

The weather data is only every 15 minutes, but I want to match it to any minute measurement, so I need to interpolate the values for each minute.

First, make a separate dataframe with every minute for each of those days.

```
all_times <- data.frame(collect_date_time = c(# April 5
                           seg(from = as.POSIXct("2021-04-05 10:00"),
                                to = as.POSIXct("2021-04-05 16:00"),
                               by="min"),
                           # April 19
                           seq(from = as.POSIXct("2021-04-19 10:00"),
                               to = as.POSIXct("2021-04-19 16:00"),
                               by="min"),
                           # April 26
                           seq(from = as.POSIXct("2021-04-26 10:00"),
                               to = as.POSIXct("2021-04-26 16:00"),
                               by="min"),
                           # May 3
                           seq(from = as.POSIXct("2021-05-03 10:00"),
                               to = as.POSIXct("2021-05-03 16:00"),
                               by="min"),
                           # May 10
                           seq(from = as.POSIXct("2021-05-10 10:00"),
                               to = as.POSIXct("2021-05-10 16:00"),
                               by="min"),
                           # May 17
                           seq(from = as.POSIXct("2021-05-17 10:00"),
                               to = as.POSIXct("2021-05-17 16:00"),
                               by="min")
                           ))
```

Next, merge the weather data into the times dataframe and interpolate the temperature and humidity between measurements.

```
all_times_weather <- all_times %>% # time only dataframe
  # add weather measurements based on matching date-time
  left_join(weather, by = 'collect_date_time') %>%
  # convert temperature units, thanks America
  mutate(temp_C = fahrenheit.to.celsius(Temperature_F, round = 2),
         # interpolate temperatures
         temp_C_interpol = na.approx(temp_C),
         # interpolate humidities
         RH_percent_interpol = na.approx(RH_percent),
         # interpolate Wind Speeds
         Wind_mph_interpol = na.approx(Wind_Speed_mph),
         # interpolate solar radiation
         Solar_rad_Wm2_interpol = na.approx(Pyranometer_W_m),
         # compute VPD
         temp_K_interpol = temp_C_interpol + 273.15,
         e_s_kPa_int = 0.611*exp((2500000/461.5)*
                                  ((1/273)-(1/temp_K_interpol))),
         e_a_kPa_int = e_s_kPa_int * (RH_percent_interpol/100),
         VPD_kPa_int = e_s_kPa_int - e_a_kPa_int
         ) %>%
  # keep only the relevant variables
  dplyr::select(collect_date_time,
                temp C interpol,
                RH percent interpol,

## Compute Scaled Mass Index

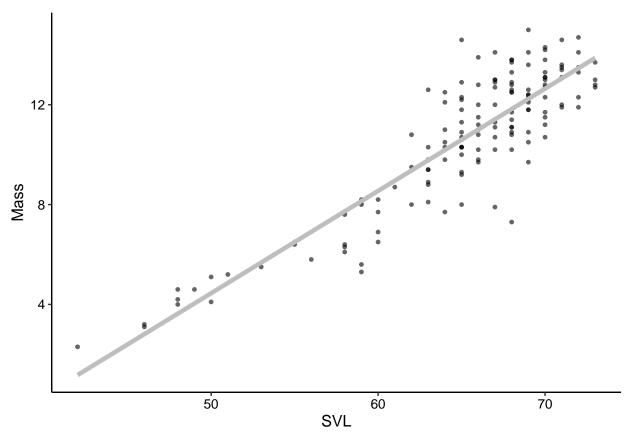

This is also known as the body condition index, or log-log residuals.

I calculate as described by: Peig, J., & Green, A. J. (2009). New perspectives for estimating body condition from mass/length data: The scaled mass index as an alternative method. Oikos, 118(12), 1883–1891. https://doi.org/10.1111/j.1600-0706.2009.17643.x

### Step 1: mass $\sim SVL$

plot:

```
morpho_blood_dat %>%
  ggplot(data = .) +
  geom_point(aes(x = SVL_mm,
                 y = mass_g,
                 ),
             size = 1,
             alpha = 0.6) +
  stat_smooth(aes(x = SVL_mm,
                  y = mass_g,
                  ),
              formula = y \sim x,
              method = "lm",
              color = "gray",
              se = F,
              size = 1.6,
              alpha = 1) +
  theme_classic() +
  xlab("SVL") +
  ylab("Mass") +
  theme(text = element_text(color = "black",
                            family = "sans",
                            size = 12),
        axis.text = element_text(color = "black",
                                 family = "sans",
                                 size = 10),
        legend.text.align = 0
```

create a simple linear regression

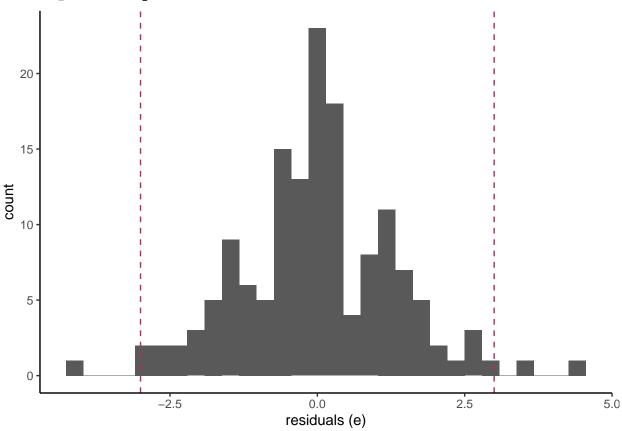

```
mass_SVL_SLR <- lm(data = morpho_blood_dat, mass_g ~ SVL_mm)
summary(mass_SVL_SLR)
##
## Call:</pre>
```

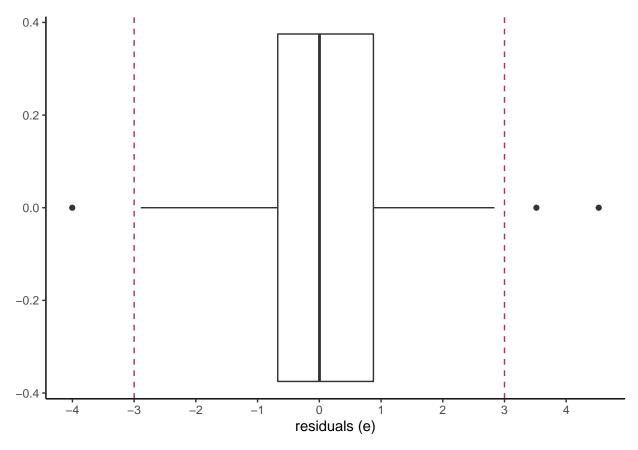

```
## lm(formula = mass_g ~ SVL_mm, data = morpho_blood_dat)
##
## Residuals:
       Min

##
## Residual standard error: 1.316 on 146 degrees of freedom
## Multiple R-squared: 0.7895, Adjusted R-squared: 0.7881
## F-statistic: 547.7 on 1 and 146 DF, p-value: < 2.2e-16
```

look for outliers by calculating residuals

#### plot residuals

## `stat\_bin()` using `bins = 30`. Pick better value with `binwidth`.

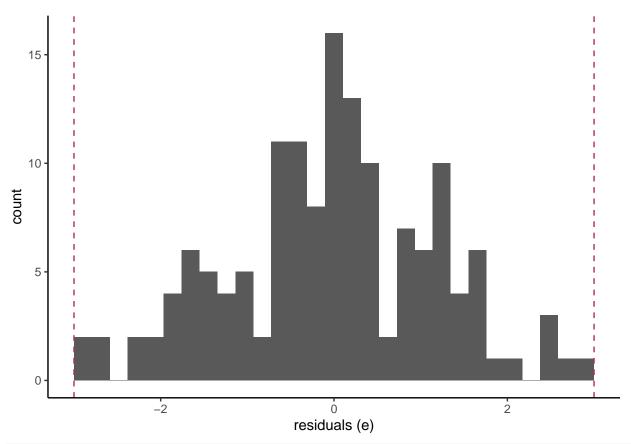

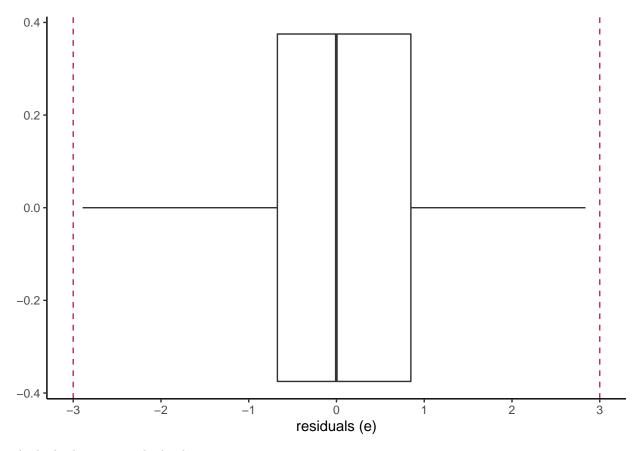

From the histogram, there are clearly points disconnected from the main curve. In the boxplot, we can distinguish that those outlying points have residuals <-3.5 and >3, so I'll go back and filter those out in the code chunk before making the distribution plots. Now the boxplot has no dots outside the main distribution.

calculating residuals with outliers excluded

plot new residuals

## `stat\_bin()` using `bins = 30`. Pick better value with `binwidth`.

And, check mean residual value:

```
## mean_res med
## 1 -0.02769117 -0.00174
```

Not zero, which is not ideal, but pretty close.

Next, check for high leverage points:

```
## date collect_time individual_ID SVL_mm mass_g sex_M_F ## 1 2021-04-05 2021-12-18 10:38:00 4 48 4.2 M
```

```

```

The points for individuals 4, 5, 6, 8, 9, 57, 64, 67, 87, and 123 seem to be high-leverage, so we will try removing them.

Check for influential points based on Cook's distance:

```
left_join(., cooks, by = "row")
# see moderately influential points
cook_mod_inf <- influential %>%
  dplyr::filter(c>0.5)
cook_mod_inf
##

## <0 rows> (or 0-length row.names)
There are no even moderately-infuential points, at least based on Cook's distance, so there's nothing to
potentially remove.
Create new SLR and check mean residual value after removing outliers and high leverage points:
# create new dataframe with filtered data
cleaned_SMI_dat <- mass_SVL_SLR_residuals2 %>% # already w outliers removed
  mutate(row = rownames(.)) %>%
  # add high leverage point info
 left_join(., high_leverage, by = "row") %>%
  # remove high leverage points
  dplyr::filter(H < h_bar)</pre>
# model
mass_SVL_SLR2 <- lm(data = cleaned_SMI_dat, mass_g ~ SVL_mm)</pre>
summary(mass_SVL_SLR2)
##
## Call:
## lm(formula = mass_g ~ SVL_mm, data = cleaned_SMI_dat)
##
## Residuals:
##
        Min

                       Median
                                     3Q
                                             Max
## -2.72134 -0.88611 0.00146 0.70819 2.87193
##
## Coefficients:
##
                Estimate Std. Error t value Pr(>|t|)
                            1.28410 -13.49
                                               <2e-16 ***
## (Intercept) -17.32109
## SVL_mm
                 0.42953
                            0.01953
                                      21.99
                                               <2e-16 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 1.209 on 133 degrees of freedom
## Multiple R-squared: 0.7843, Adjusted R-squared: 0.7827
## F-statistic: 483.6 on 1 and 133 DF, p-value: < 2.2e-16
# compute residuals
mass_SVL_SLR2_residuals <- cleaned_SMI_dat %>%
  mutate(y_hat = predict(mass_SVL_SLR2),
         e = residuals(mass_SVL_SLR2))
```

# check residuals values

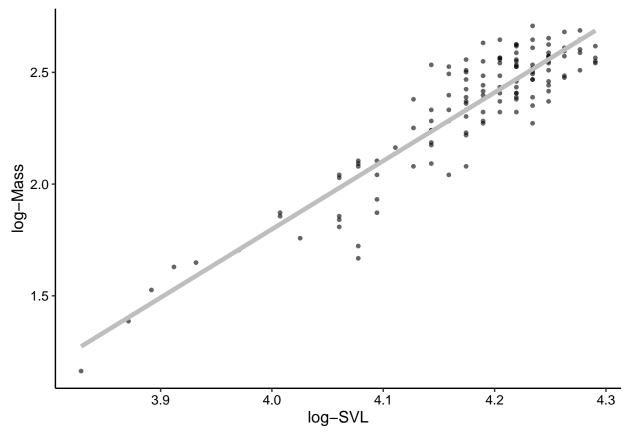

```
## mean_res med
## 1 4.654038e-17 0.001458016
```

The residuals are much much smaller, so I believe it is the right choice to remove the high leverage points. The "cleaned\_SMI\_dat" will be used to calculate the equation for SMI.

#### Step 2: make log-log relationship

plot and calculate SLR for filtered data

```
cleaned_SMI_dat %>%
  ggplot(data = .) +
  geom_point(aes(x = log(SVL_mm),
                 y = log(mass_g),
                 ),
             size = 1,
             alpha = 0.6) +
  stat_smooth(aes(x = log(SVL_mm),
                  y = log(mass_g),
                  ),
              formula = y ~ x,
              method = "lm",
              color = "gray",
              se = F,
              size = 1.6,
              alpha = 1) +
  theme_classic() +
  xlab("log-SVL") +
 ylab("log-Mass") +
  theme(text = element_text(color = "black",
                            family = "sans",
                            size = 12),
        axis.text = element_text(color = "black",
                                 family = "sans",
                                 size = 10),
       legend.text.align = 0
```

```
SLR
```

b\_OLS <- 3.0611 # regression slope

```
log_mass_SVL_SLR <- lm(data = cleaned_SMI_dat,</pre>
                       log(mass_g) ~ log(SVL_mm))
summary(log_mass_SVL_SLR)
##
## Call:
## lm(formula = log(mass_g) ~ log(SVL_mm), data = cleaned_SMI_dat)
##
## Residuals:
##
        Min
                  1Q
                       Median
                                    3Q
   -0.36738 -0.07518 0.00334 0.06423 0.29781
##
## Coefficients:
##
               Estimate Std. Error t value Pr(>|t|)
## (Intercept) -10.4465
                            0.4858
                                   -21.50
                                              <2e-16 ***
                                     26.34
                                              <2e-16 ***
## log(SVL_mm)
                 3.0611
                            0.1162
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## Residual standard error: 0.1175 on 133 degrees of freedom
## Multiple R-squared: 0.8391, Adjusted R-squared: 0.8379
## F-statistic: 693.6 on 1 and 133 DF, p-value: < 2.2e-16
compute standardized major axis using this regression equation:
r <- sqrt(0.8391) # Pearson's correlection coefficient (sqrt of R-squared)
```

```
b_SMA <- b_OLS/r
also get a value for L0:
L0 <- mean(cleaned_SMI_dat$SVL_mm)
```

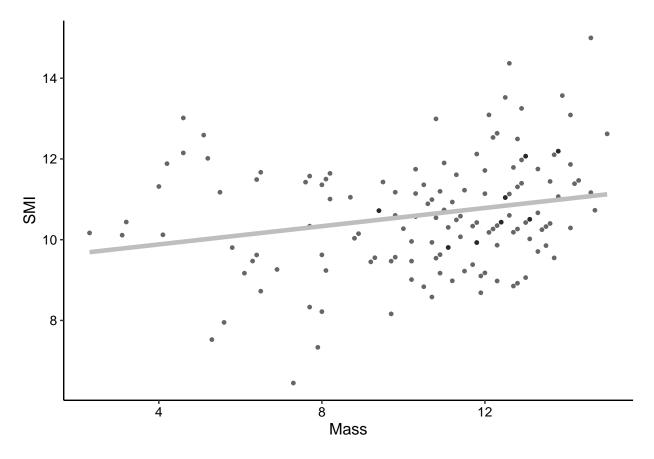

#### Step 3: calculate scaled mass index

(And join weather data.)

#### Check

Look at the difference between regular mass and SMI:

```
morpho_blood_SMI %>%
  ggplot(data = .) +
  geom_point(aes(x = mass_g,
                 y = SMI,
                 ),
             size = 1,
             alpha = 0.6) +
  stat_smooth(aes(x = mass_g,
                  y = SMI,
                  ),
              formula = y \sim x,
              method = "lm",
              color = "gray",
              se = F,
              size = 1.6,
              alpha = 1) +
  theme_classic() +
  xlab("Mass") +
  ylab("SMI") +
  theme(text = element_text(color = "black",
                            family = "sans",
                             size = 12),
        axis.text = element_text(color = "black",
                                  family = "sans",
                                  size = 10),
        legend.text.align = 0
```

#### Join Data

Add CEWL and morpho\_blood\_SMI data together.

```
##
         date
                               Time
                                               individual_ID region

```

#### Conclusion

Osmolality and SMI were the only normally distributed variables.

The following variables each had non-normal distributions: - SVL (skewed left) - mass (skewed left) - hct (looks like a bell curve, but not very pretty) - cloacal temp (skewed right) - CEWL (skewed right, overall and for each region individually) - capture temp (multimodal) - wind speed (multimodal but sorta bell curve) - solar radiation (multimodal)

All of the non-normal variables are likely to need transformation if they're included in the final model.

        axis.text = element_text(color = "black", family = "sans", size = 10),
        legend.text.align = 0,
        legend.position = "none"
)
```

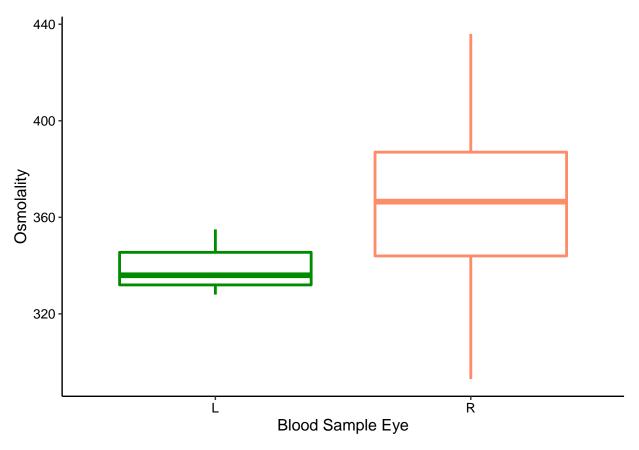

## Warning: Removed 27 rows containing non-finite values (stat\_boxplot).

### $Osml \sim Sample \ Eye$

```
morpho_blood_SMI %>%
  dplyr::filter(blood_sample_eye %in% c("R", "L")) %>%
  ggplot(data = .) +
  geom_boxplot(aes(x = blood_sample_eye,
                   y = osmolality_mmol_kg,
                   color = blood_sample_eye
                   ),
               size = 1,
               alpha = 0.6) +
  scale_colour_manual(name = "Blood Sample Eye",
                      values = c("green4", "salmon1") ) +
  theme_classic() +
  xlab("Blood Sample Eye") +
  ylab("Osmolality") +
  theme(text = element_text(color = "black", family = "sans", size = 12),
        axis.text = element_text(color = "black", family = "sans", size = 10),
        legend.text.align = 0,
        legend.position = "none")
```

## Warning: Removed 3 rows containing non-finite values (stat\_boxplot).

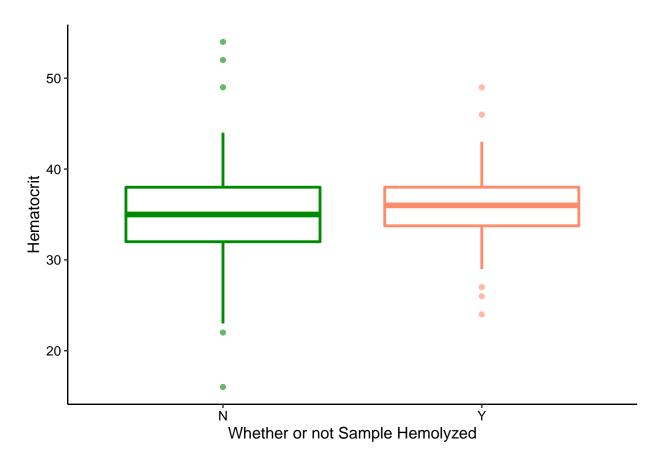

There IS a significant difference, but upon further inspection, the number of blood draws taken from the right postorbital sinus vs left or both is so uneven, this would be unhelpful in the actual model.

#### $Hct \sim Hemolyzed/Not$

```
morpho_blood_SMI %>%
  dplyr::filter(hemolyzed %in% c("Y", "N")) %>%
  ggplot(data = .) +
  geom_boxplot(aes(x = hemolyzed,
                   y = hematocrit_percent,

```

Osmolality was VERY different by week, and that was not easily attributable to climate factors (see below). We also experienced technical difficulties with the osmometer between some weeks, so some of the variation may be attributable to technical error. Thus date/week will be a good random factor to include in the LMM.

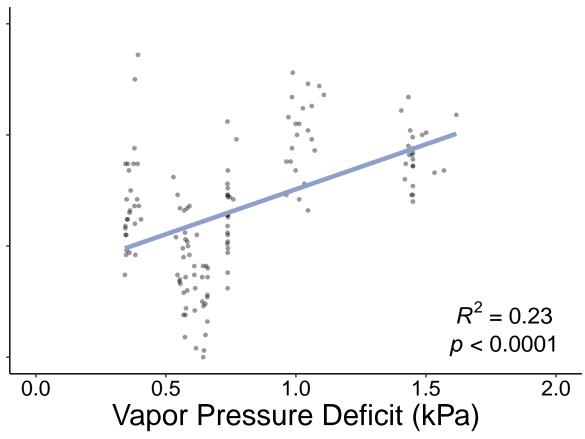

distinguish pairwise differences using an ANOVA:

```
95% family-wise confidence level

#### Selection

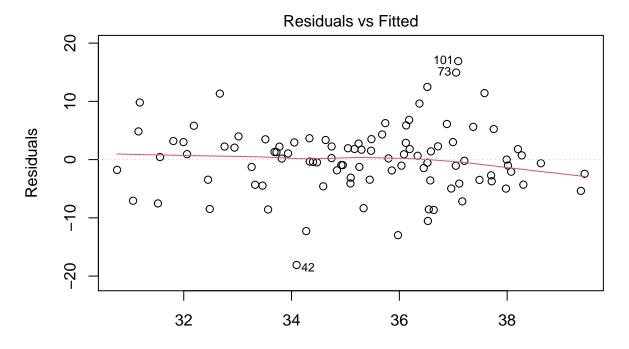

models 4-11 and the null model are the ones we should compare. models 1-3 had serious multicollinearity thus are not trustworthy models.

```
hct_models <- list(hct_mod4, hct_mod5, hct_mod6, hct_mod7,</pre>
                    hct_mod8, hct_mod9, hct_mod10, hct_mod11,

residuals all look fine

# Export

We should save the information for the top three models, as well as the table showing the rankings of the different models.

## Hydration

#### Models

Start with all the variables that may explain osmolality variation. Female gravidity cannot be included because of the low sample size and number of contrasts.

Selection
models 4-9 and the null model are the ones we should compare. models 1-3 had serious multicollinearity thus
are not trustworthy models.

The predictors in this model are much less collinear. Now we will begin model selection using AIC and t-values.

Need dataset without NAs first.

# Check LM Assumptions

## plot(CEWL\_mod16)

plot(CEWL\_mod17)

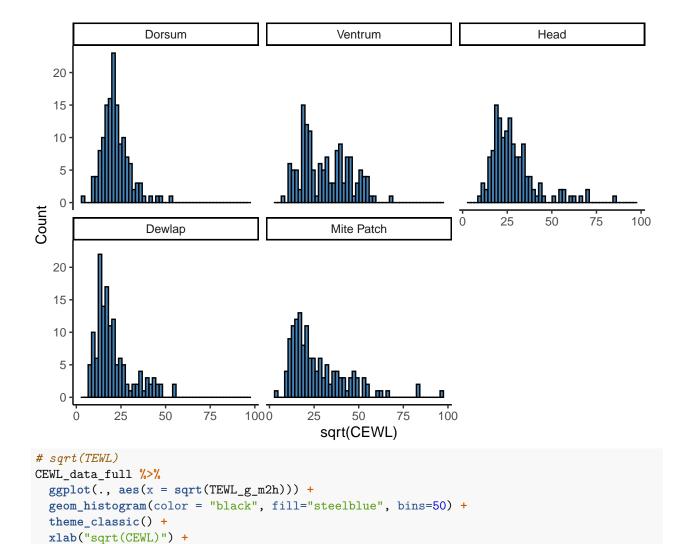

Both have fanning, which indicates that linearity and equal error variance are not satisfied.

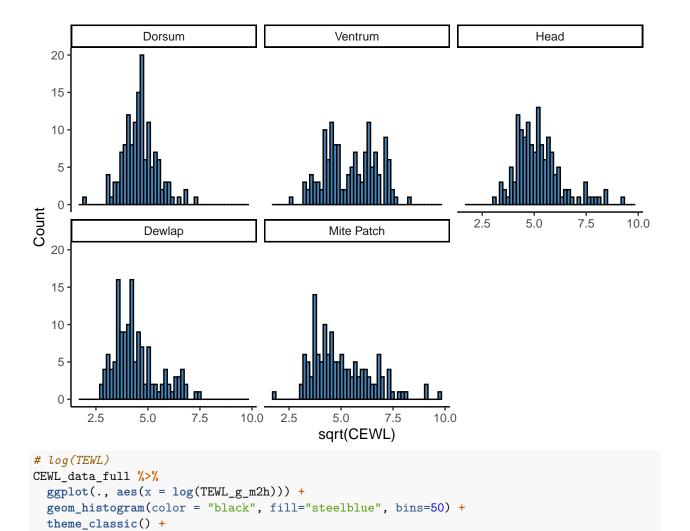

## Test Transformations

Can I improve satisfaction of LM assumptions by transforming the dependent variable? In particular, conditions of linearity and normality are not met.

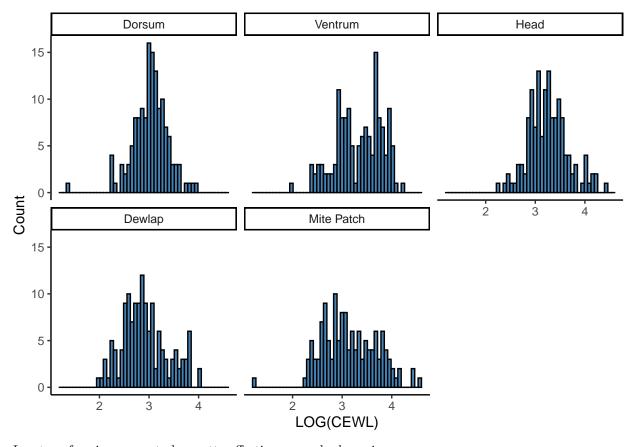

```
# normal TEWL
CEWL_data_full %>%
    ggplot(., aes(x = (TEWL_g_m2h))) +
    geom_histogram(color = "black", fill="steelblue", bins=50) +
    theme_classic() +
    xlab("sqrt(CEWL)") +
    ylab("Count") +
    facet_wrap(~region)
```

ylab("Count") +
facet\_wrap(~region)

xlab("LOG(CEWL)") +
ylab("Count") +
facet\_wrap(~region)

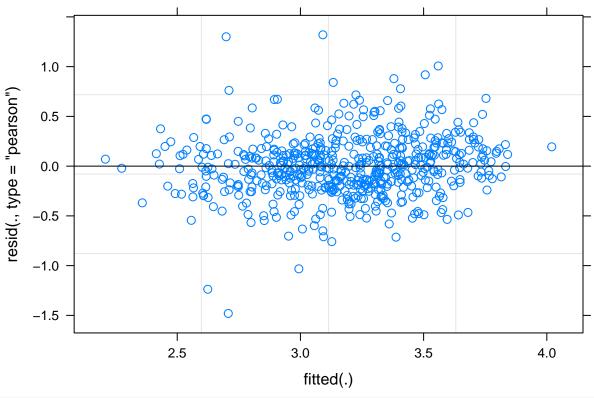

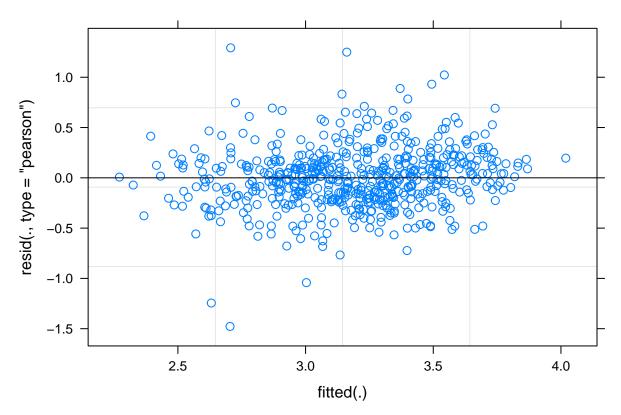

Log transforming seems to be pretty effective across body regions.

# Transform & Re-Model

I will log-transform CEWL and see whether it makes the models satisfy LMM assumptions better.

Run top 2 CEWL models with log-transformed CEWL:

MUCH better! These models are good.

Re-select model data for only the variables included in the final models:

```
CEWL_dat_sub2 <- CEWL_data_full %>%
  dplyr::filter(complete.cases(region,
                                VPD_kPa_int,
                                Solar_rad_Wm2_interpol,
                                mass_g,
                                cloacal_temp_C,
                                ambient_temp_C, temp_C_interpol,
                                VPD kPa))
CEWL_mod16tp <- lmerTest::lmer(data = CEWL_dat_sub2,</pre>
                          # response variable
                          log(TEWL_g_m2h) ~
                          # potential predictors
                          region * (VPD_kPa_int + mass_g) +
